CCRMA

What is the SP-12

- Drum machine sampler and sequencer
- 27.5 kHz sampling rate (F_s)
- 192 kB wavetable RAM
 - Total 5 sec
 - Each continuous sound limited to 2.5 sec
- 24 internal sounds loaded from ROM
- 8 user sounds can be sampled from analog input
- 32 pitch adjustment (in half-steps), and decay envelope settings
- 8 output channels
 - Each with different equalization
 - Output 1, 2 are direct ZOH output
 - Outputs 7, 8 have dynamic filter (VCF), constant Q, exponentially swept F_c
- Often used as signal processing for drum sounds to add a “hard edge” or “grit”

CCRMA

Digital Model of the SP-12

- Analyze signal path of the SP-12
- Implement digitally
 - Anti-aliasing filter
 - Quantization
 - Sampling
 - Tuning and decay envelope
 - Zero Order Hold
 - Time varying filter (Voltage Controlled Filter)

CCRM

Anti-Alias and Equalization Filters

- Fixed filters – no parameters
- Analyzed in SPICE
 - AC simulation
 - Export frequency response of input to output transfer function
- Design filters in Matlab
 - Use `invfreqz` to design digital filter
 - Increase order until good fit in band
 - Oversample at 96 kHz for easier fit
- Input anti-alias filters: 6th order
- Excellent fit through 20 kHz for input anti-alias at order 11. Lower orders may be sufficient as well.
- At $F_s/2=13.75$ kHz, only -10 dB attenuation -> significant aliasing

CCRM

Output Equalization Filters

- Output equalization are 2 stage Sallen-Key active filters.
 - Total of 4th order.
 - $F_s = 48$ kHz
 - 4th order fit is good through 20 kHz.
- Attenuation at $F_s/2 = 13.75$ kHz is -23 dB
 - Incomplete rejection of spectral images

CCRM

Ideal interpolation and sampling

- Signal processing rate is 96 kHz. Must convert to 27.5 kHz, and simulate the sampling process with correct aliasing.
- Interpolate to time grid of 27.5 kHz
 - Resample to multiple of 27.5 kHz for oversampling
- Downsample directly with no additional anti-alias filter
 - Previously anti-aliased by SP-12's filter

CCRM

A/D conversion

- Successive approximation
 - Binary search for analog signal in digital representation
- Assumed ideal due to accuracy of process
 - Single comparator, D/A usually accurate
- 6 dB per bit, 12 bits = 72 dB SNR
- Quantization generates harmonic distortion

CCRM

D/A conversion: Zero Order Hold

- Convolution of samples with delayed *rect*
- Staircase output – Much aliasing remains

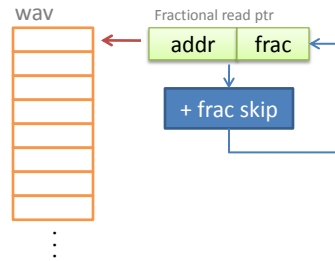

Zero Order Hold

- Zero Order Hold (ZOH)
- Simple method of D/A conversion (converts impulse train to continuous time signal)
- Digitally, repeat each sample N times
- Equivalently, filtering by a frequency aliased sinc
 - Sinc plotted to 20 kHz for various discrete-time rect of width N.
- Digital ZOH has frequency domain error, but is inherently oversampled to minimize errors at lower frequencies
 - At N=4, error through 20 kHz is <0.5dB

Drum tuning

- Waveform table is held in memory
- Move read pointer by a fractional amount and round or truncate to nearest address
- Creates complicated aliasing type patterns and introduces high pitched components to sound character

CCRM

Spectrograms of tuning algorithm

- Linear sweep from 0-20kHz.
- Fractional tunings produce various granularities of chain-link-fence-like patterns
- Tuning algorithm also changes length of waveform
- SP-12 has 32 different tuning settings with various skip amounts

CCRM

Dynamic filters

- Voltage controlled filter
 - Essentially a Moog VCF with the transistors integrated onto a single chip
 - Configured for constant Q
 - Approximately exponential cutoff frequency trajectory
- Matlab implementation
 - Digital Moog implementation (Stilson 96, Valimaki 06)
 - Exponential time constant = 0.085 s
 - Initial $F_c = 14150$
 - Final $F_c = 1150$
- Noise sweeps of SP-12 (top) and Matlab (bottom)

Sound examples

- Physical modeling produces accurate results capturing much of the character of the real thing.
- When device and schematics are available, reimplementing the functionality digitally requires little or no tweaking.
